

Pick Card

Firstly, the server notifies the active player (promptCurrentPlayer method).
The outer loop repeats until all players have resolved their turn
(then a transition to the next state will occur).
The inner loop handles client-side validation:
If the player's turn, or IDs are **invalid** - **showError** is called immediately.
Once all checks pass, resolveOfferTileAction() is sent to the Model.

Two index lists are used because some files allow picking from **both rows simultaneously**.
We also send the List of the requested Card to know in which order the card were picked
(e.g. picking a builder before the building reduce the food cost of the building)
The server validates as well the action, updates the Model, and notifies all clients.
Finally, resolveNextMacroState() advances the game to the next phase.
