

Pick Card

The server notifies the active player, then the View highlights pickable cards.
The outer loop repeats until all players have resolved their turn (then a transition to the next state will occur).
The inner loop handles client-side validation:
If the player's turn, card count, IDs, or food are **invalid**:
showActionErrorCode is called immediately.
Once all checks pass, **resolveOfferTileAction()** is sent to the Model.
Two index lists are used because some tiles allow picking from **both rows simultaneously**.
The server re-validates, updates the Model, and notifies all clients.
Finally, **resolveNextMacroState()** advances the game to the next phase.
